Malignant pleural mesothelioma is an aggressive cancer with a high mortality rate and a lack of effective treatment. Our aim is to conduct a phase I trial to test the safety and efficacy of local administration of an adenoviral vector-containing interleukin-24 gene in advanced pleural mesothelioma patients. Tumor samples from 17 patients with advanced mesothelioma were subjected to analysis for the presence of human mesothelioma genes (K-ras and p53). Human mesothelioma cells were isolated from pleural effusions of patients with mesothelioma and cultivated in vitro. A replication-incompetent adenoviral vector containing the interleukin-24 gene (Ad-IL-24) was constructed and used for in vitro infection of mesothelioma cells. In vivo administration of Ad-IL-24 was tested in mesothelioma xenograft-bearing severe combined immunodeficient mice. The adenoviral vectors were administered to seven patients with inoperable mesothelioma who had residual disease after pleurectomy. The patient was considered to have achieved a complete response (CR) when a lung scan showed no abnormal focal uptake greater than that of the background level. The other 10 patients with advanced mesothelioma were treated with gemcitabine because they were ineligible for surgical resection and had progressive disease despite chemotherapy. Five patients had a decrease in the mesotheli
