The Internet is definitely taking over for a lot of things, and one of those things is searching for files, thanks to the ever-expanding (and painfully slow) Google index. There are a lot of file hosting sites out there, but we're focused on the. Unless you're a. The long term goal is to understand the neural basis of vocal control and its impairment. Three neural systems are critical for vocalization: the autonomic nervous system (ANS), the primary motor cortex, and the ventral lateral geniculate nucleus (LGN). All are crucial for the initiation and regulation of vocalization, but their functional contributions are still unclear. The immediate aim is to investigate the contribution of the ventral lateral geniculate nucleus to vocalization. The functional contributions of the different LGN inputs to motor cortex, and of LGN inputs to ANS through the spinal cord will be evaluated by disrupting functional connectivity via chemogenetic or optogenetic means. The general hypothesis is that the input to the motor cortex from the ventral lateral geniculate nucleus mediates vocalization; or that the input from the motor cortex to the ventral lateral geniculate nucleus regulates the initiation of vocalization. Anatomical connectivity data will be used to support the hypothesis that the input to motor cortex is primarily direct through the thalamus, as well as to suggest alternative pathways. Blocking output from LGN during vocalization will be done to identify the part of the pathways that are responsible for vocalization, and the contribution of direct input vs. indirect input via motor cortex will be evaluated.
